**Let's Start!****All About Switch Statements in Java!****Learning Outcome:**

Talk about principles, concepts, and characteristics of general-purpose computer programming language in spoken and written situations.

Ask your partner:

- How does computer programming language Java work?
- What do you know about the syntax of switch statements in Java?

Can Do Statements:

- I can say what the switch statement is in Java.
- I can talk about the syntax of a switch statement in Java.
- I can discuss examples of switch statements in Java.

Let's Explore!

Do you know what is a switch statement?

Instructions: Read the text below.

Computer programming languages, such as Java, has got to work with switch statements. These are control mechanisms that branch a program and speed up a decision making process. For instance, think about a command and type it, what is going to happen next is that this command has got to go to a position in the switch statement. These go-to positions are also known as case labels, which are going to have to emit constant values that have got to be the same as switch expressions. In case these ones don't match, there is a default keyword at the end of the statement that captures this fallout and avoids an invalid input in the program execution.

On the other hand, the syntax of a switch statement in Java consists of patterns that establish the different commands and codes to execute a function. The syntax of switch statements is considered very effective since it allows the program to find expressions in an accurate way, without checking statement by statement. So, next time, do not worry about the math function but about the structure of the statement. And remember that sometimes break statements are necessary to help the program to skip the switch statement ending.

To conclude, take a look at these examples. First, imagine a code where you have got to register a particular number to perform a task. Now, imagine that the program finds a different number that doesn't agree with the code. What the program is going to have to do is to skip the default function and stop immediately. Then, go to your computer and select a game. Once you start playing it, the computer is going to have to determine certain paths within the switch statements depending on your choices.

Let's Practice!

Include the switch statement in the setting.

Instructions: Use the words from the box to correctly complete the sentences.

Set / Decrease / Use / Switch

1. _____ the switch statement instead of an extended if statement.
2. _____ computational time by replacing a nested code with the switch statement.
3. _____ to a case level by evaluating the expression.
4. _____ a default key word at the end to avoid invalid inputs.

Let's Practice!

Switch Statements in JAVA

Instructions: Circle the correct option to complete the sentences.

1. The syntax _____ all the cases you need.
a. have included
b. has to include
2. You _____ add a default option for the program not to fail.
a. 's having to
b. are going to have to
3. You _____ set the break statements.
a. don't have to
b. has to
4. The syntax _____ only one of the expressions.
a. has to switch
b. going to switch

Extension Activity

The switch statement

Instructions: Complete the following steps. Fill in the Self-Assessment.

- Design a switch statement for any program you want.
- Write a text explaining the statement and how you created it. Use the imperatives to describe it, and the "have to" and "going to have".
- Share with your partners.

Self-Assessment

Yes

No

- I use the switch statement and explain how to set it.
- I explain what the switch statement is.
- I design and explain how to design a switch statement.

☐ ☐
☐ ☐
☐ ☐

Target Words

- speed up** (phrasal verb): to accelerate a process
e.g. These are control mechanisms that branch a program and speed up a decision making process.
- type** (verb): to write on a computer's keyboard
e.g. Think about a command and type it.
- label** (noun): a tag that classifies something depending on its particular characteristics
e.g. These go-to positions are also known as case labels.
- emit** (verb): to send out, to transmit
e.g. Case labels are going to have to emit constant values that have got to be the same as switch expressions.
- match** (verb): to agree or coordinate with something
e.g. In case these ones don't match, there is a default keyword at the end of the statement.
- fallout** (noun): an unexpected consequence
e.g. The default keyword captures this fallout and avoids an invalid input in the program execution.

Learning Points

Imperatives

You use the **imperative** to give instructions, advice or interdictions.

The imperative is a direct mode, so you don't need to use a subject pronoun.

Affirmative structure

Main verb in base form + complement

Examples:

- **Type** a code in the switch statement.
Skip that command.

Negative structure

Auxiliary DO + not + main verb in base form + complement

Examples:

- *Do not type a code in the switch statement!*
- *Don't skip that command!*

Examples

- *Think about a command and type it.*
- *Next time, do not worry about the math function but about the structure of the statement.*
- *Imagine that the program finds a different number that doesn't agree with the code.*

Learning Points

Have Got to and Going to Have to for What Is Necessary

You use “*Have got to*” and “*Going to have to*” to express the necessity to perform a particular action.

Have got to

It has the same meaning of **have to**; however, it is a little bit more formal.

To make statements with **have got to** you follow this structure:

S + **Have/Has** + **Got to** + Main verb in base form + Complement

Examples:

- We **have got to** work with switch statements.
- The engineer **has got to** check the values.

As you can see, you conjugate “have got to” with the subject pronouns (I, you, we and they) and “has got to” with the subject pronouns (He, She and It).

Going to have to

In the case of **Going to have to**, it is quite similar to **Going to need to**.

To make statements with **going to have to** you follow this structure:

S + To be verb + **going to have to** + Main verb in base form + Complement

Examples:

- We **are going to have to** work with switch statements.
- The engineer **is going to have to** check the values.

As you can see, you conjugate the verb **be** depending on the subject pronoun. But “going to have to” remains the same

Examples

- *This command has got to go to a position in the switch statement.*
- *Imagine a code where you have got to register a particular number to perform a task.*
- *These go-to positions are also known as case labels, which are going to have to emit constant values that have got to be the same as switch expressions.*
- *What the program is going to have to do is to skip to the default function and stop immediately.*
